Q1: How does the system use symptoms like fever, chills, or muscle pain to figure out possible diseases and suggest a doctor?

Please select one of the options to know more about it.

Select your answer:

- ○ It combines votes from many decision trees to decide the most likely disease, then another model connects that disease to the right doctor.
- ● It directly picks the disease that shows up first in its database and pairs it with the nearest available doctor.

❌ Incorrect.

Option 2 has been selected.

It looks like you've chosen Option 2. Unfortunately, that's not how our system works.

Our system doesn't simply pick the first disease it finds in its database or pair it with the nearest available doctor. Instead, it uses a more complex approach to figure out possible diseases and suggest a specialist.

Let me break it down: when you input symptoms like fever, chills, or muscle pain, our system uses a Random Forest model to analyze these symptoms and predict the most likely diseases. This model combines the "votes" from many decision trees to decide on the top diseases that might be causing your symptoms.

Q1: Why does the system use both cosine similarity and LDA topic modeling for David Chen's advisor recommendations?

Please select one of the options to know more about it.

Select your answer:

- ○ To increase computational complexity
- ● To provide a robust match by combining keyword and thematic alignment

✅ Correct!

Option 2 has been selected.

The system uses both cosine similarity and LDA topic modeling for David Chen's advisor recommendations because it aims to provide a robust match by combining keyword and thematic alignment.

Let me explain how this works: Cosine similarity measures the similarity between two vectors (in this case, David's research interests and the advisors' areas of expertise) based on their keywords. It's useful for identifying advisors who have similar keywords in their profiles.

LDA topic modeling, on the other hand, is a technique that identifies underlying themes or topics in a large corpus of text. In this system, LDA helps to identify the dominant topics in an advisor's research and matches them with David's interests at a more thematic level.

By combining both methods, the system can provide a more comprehensive match. Cosine similarity ensures that the recommended advisors have similar keywords, while LDA topic modeling ensures that they also align with David's research themes. This dual approach increases the chances of finding the best possible advisor for David.
